Abstract

Aim: To evaluate the possibility of air dried smear and rehydration with corn syrup instead of conventional method.

Materials and Methods: 20 paired buccal smear taken from the healthy individual. One set labelled as wet fixation with 95% ethanol and other set labelled as dry fixation with rehydration with corn syrup. They were graded blindly.

Results: Statistically significant similarities were seen between the two groups in terms of cellularity and staining intensity.

Conclusion: The procedure of air drying and rehydration with corn syrup is inexpensive, easy, convenient technique and almost equally effective to routine fixation.

Keywords: Diagnosis; Cytology; Epithelial cells; Microorganism

Introduction

Smear as a useful method for early detection of cancerous lesions and inflammatory conditions is routinely carried out worldwide. Exfoliative cytology is an minimally technique for obtaining cells to role out the diagnosis. One alternative method for overcoming the problem of poor fixation, introduced over half a century ago, is air-drying followed by rehydration and fixation before staining.

Objective

To evaluate rehydration with corn syrup can be adopted as an alternative technique.
Results

Figure 1 Staining showing difference between Alcohol fixation and corn rehydration.

Discussion

Air dried technique first described by Lencioni in Studies with attempts on the improvement of rehydration techniques by experiments on the various rehydration agents and variable duration of air-drying before smear rehydration have been subsequently reported [1-3]. In most studies, the quality of rehydrated air-dried smears was either equal or superior to wet-fixed smears. Thus, Air-dried technique was suggested as a potential alternative to wet fixation for mass screening of cytology.

Table 1 Statically significant similarities were seen between the two groups in terms of preservation and staining intensity. P value of this study is P<0.01.

Rehydration of air-dried smear has not been widely practiced probably due to unfamiliarity with the technique and the feeling of uncertainty about specimen satisfaction. Among several reagents for rehydration of air-dried smears with satisfactory results.

In the present study, preservation of the cytoplasmic quality was satisfactory in all AD and WF smears although excellent cytoplasmic staining was slightly more frequent in WF group.

Regarding nuclear staining quality, previous studies reported no significant difference between AD and WF smears. When the nuclear morphology of squamous epithelial cells was separately evaluated in the present study, the staining quality of squamous nuclei was slightly lower in AD smears than in WF smears.

Although the frequency of cases affected by air-drying artifact and decreased nuclear quality were significantly more frequent in AD smears.

These factors did not interfere with the overall cytologic evaluation because they occurred in a minor degree and in the minority of cells in each individual smear. All AD smears were considered satisfactory for cyto-morphologic evaluation.

Among 20 paired slides in both the group was satisfactory. Processing seen poor due to DPX mounting not proper 2%-3% in alcohol fixation and 4-5% in corn rehydration, Nuclear staining 9%-10% seen faded in both solutions Cytoplasm staining 10%-13% seen vaculization and irregular staining which mostly found in corn rehydration.

Background staining is again almost equal in both the solution i.e; 94%-92% seen micro-organism and some inflammatory cells also present.

Conclusion

All the smears in both group was satisfactory, it shows good fixation and also good staining intensity of oral squamae cells and background. The procedure of air drying and rehydration with corn syrup is inexpensive, easy, convenient technique and almost equally effective to routine fixation. The simplicity of the technique and the easiness in smear transportation without the use of alcohol also offer potential advantage for its application.
